

Project Design Phase

Overall Design

The project is designed as a record-level security solution in ServiceNow. The Institution Details table stores the information, while ACLs determine which operations can be performed by different users.

Table Design

The Institution Details table contains student and faculty references, branch information, and contact details. The Branch field is the main field used for the READ access restriction.

Role Design

Four roles are used in the access model. bb1 is associated with READ access, bb2 with CREATE, bb3 with WRITE, and bb4 with DELETE. This separates permissions for individual operations.

ACL Design

A separate record ACL is created for each operation. The READ ACL uses the EEE branch condition and an advanced script. The CREATE, WRITE, and DELETE ACLs use their respective required roles and do not use a data condition.

Script Design

The READ script checks the admin role first and permits access to administrators. It then checks whether the user has bb1. If neither condition is satisfied, the script returns false and access is denied.

Access Flow

The access flow is based on the current user's roles and the operation being performed. For READ access, the Branch condition and advanced script are additionally evaluated before access is granted.
