

Project Planning Phase

Project Objective

The objective is to build and validate a ServiceNow ACL configuration that controls record access according to user roles and the Branch field.

Planned Work

The work starts with creating the test user and roles. The custom Institution Details table is then created with its required fields and sample records. ACLs are configured one operation at a time and validated after each stage.

Implementation Sequence

The planned sequence is user and role setup, table creation, field configuration, sample data creation, READ ACL configuration, CREATE ACL configuration, WRITE ACL configuration, and DELETE ACL configuration.

Testing Plan

Testing is performed using impersonation. The EEE User is used to verify restricted access, while the administrator account is used to confirm unrestricted access. The availability of the New button and the ability to modify or delete records are checked for the appropriate roles.

Expected Completion

After implementation, the table should have separate controls for READ, CREATE, WRITE, and DELETE operations, with the intended EEE branch restriction applied to READ access.
